How Wellstar built a truly patient-centric early lung cancer detection program

An unyielding focus on patient access and convenience to overcome care barriers

Overview

The challenge

Early lung cancer detection saves lives. However, a recent [study](#) found that just about 14.4% of eligible patients received the recommended screening exam, low-dose computed tomography (LDCT).

Additionally, the times between screening to diagnosis and diagnosis to treatment may be lengthy. One [study](#) published in 2019 found that there was a 19.2% reduction in survival in Stage I lung cancer for every six weeks until treatment was initiated.

The organization

Wellstar Health System is a large health system located in Georgia. The system includes 11 hospitals, 9 cancer centers, and 21 imaging centers among other services.

The approach

Wellstar developed a multidisciplinary lung cancer detection program that involves community provider outreach to increase screening rates, comprehensive pulmonary nodule management, and a “STAT” clinic to centralize and expedite care decisions.

The result

Wellstar’s lung cancer screening program expects to conduct 13,000 lung cancer scans in 2022 alone. Since the STAT Clinic began in 2007, they have reduced the average time from scan to diagnosis to treatment from 94 days to just 14 days.

Approach

How Wellstar built a truly patient-centric early lung cancer detection program

Lung cancer detection requires collaboration between many different specialties. Even after a suspicious finding, traditional care models require multiple patient visits. To streamline care, Wellstar gathers all the relevant clinicians to create a consensus care plan as quickly as possible.

The three elements

Wellstar's approach to building a comprehensive lung cancer detection program involves three elements:

01 Engage primary care providers and streamline referrals

02 Increase care entry points through incidental findings management

03 Reduce turnaround times through STAT clinic approach

01 Engage primary care providers and streamline referrals

Engaging patients in lung cancer screening is challenging, and nationally rates remain incredibly low. A recent [study](#) found only an estimated 14% of eligible patients received the recommended screening exam. Patients are often referred by their primary care physicians (PCPs), who play an incredibly important role in driving volume for lung cancer screening programs. But PCPs are notoriously busy, and it falls to lung cancer screening programs to ensure providers are well equipped to discuss lung cancer screening with their patients.

Wellstar's goal is to make it as easy as possible for PCPs to refer patients into lung cancer screening programs. To do this they focus on two areas:

1. Provide practical, useful education to PCPs

Wellstar leverages their physician relations team and nurse navigators to educate PCPs in their market. They focus on providing only the most critical information, such as:

- The burden of undiagnosed lung cancer in their practice, including smoking rates and lung cancer prevalence in the area
- How to record an accurate smoking history, which is required to determine patient eligibility but challenging to providers to accurately track

1. ENGAGE PRIMARY CARE PROVIDERS AND STREAMLINE REFERRALS (CONT.)

IN PARTNERSHIP WITH
The
LungAmbition
Alliance

2. Create a seamless referral experience

To assist providers in qualifying and referring patients for lung cancer screening, Wellstar developed a shared decision-making tool for clinicians and clinician assistants within their electronic health record (EHR) that pulls patient's age and smoking history to determine eligibility. For eligible patients, a best practice recommendation appears that includes a short script for providers, which may serve as the shared-decision-making visit, and one-click referral for screening.

Wellstar's lung cancer screening program takes ownership of all patient follow-up, again reducing burdens on PCPs.

02 Increase care entry points through incidental findings management

What are incidental pulmonary nodules (IPNs)?

Incidental findings are abnormalities uncovered unintentionally and unrelated to the condition that prompted an exam. Pulmonary nodules are abnormal growths that form in a lung. They can be identified on imaging scans. Most pulmonary nodules are benign, but some indicate the presence of lung cancer.

IPNs are key to a comprehensive lung cancer program

Wellstar expanded their lung cancer detection program in 2020 to more formally focus on incidental pulmonary nodule management in addition to LDCT screening. The organization invested in a tool embedded in their EHR to provide a database and tracking tool for patients with IPNs detected at Wellstar. The tool is primarily used by Wellstar's lung navigators to longitudinally track patients and coordinate recommended follow-up care.

In the first 12 months of their IPN program Wellstar detected and treated 36 lung cancers. Wellstar expects to rescan 6,000 patients in 2022 that originally entered the lung cancer detection program with IPNs (compared to 7,000 from screening).

If managed correctly, incidental findings may allow more patients with lung cancer to be diagnosed at earlier stages, providing another opportunity to help improve survival.

~46%

Patients in Wellstar's lung cancer detection program that entered with an incidental pulmonary nodule vs screening exam

03 Reduce turnaround times through STAT Clinic approach

The hallmark of Wellstar’s lung cancer detection program is their approach to reduce time from screening to treatment. Instead of fitting the patient into the clinician workflow, Wellstar built a workflow around the patient. They call this a synchronous, patient-centric approach internally branded as “STAT Clinics.”

To implement this new vision, Wellstar made two operational changes:

1. Centralized all services and clinicians involved in lung cancer detection, staging, and treatment decisions
2. Established two 7-day cycles with goals and processes for each, holding clinicians to an established timeline

Program success relies on strong patient navigators to support patients and facilitate clinician decision making.

78%

Reduction in the time from an abnormal computed tomography (CT) finding to treatment initiation with Wellstar’s STAT program approach to patient management. Represents an average decrease of 49 days.

3. REDUCE TURNAROUND TIMES THROUGH STAT CLINIC APPROACH (CONT.)

STAT Clinic Cycles

Navigators initiate both 7-day cycles, which begin with multidisciplinary consensus (MDC) meetings. Throughout these cycles navigators also provide additional administrative support, such as obtaining insurance authorizations.

WEEK 1 Diagnosis and staging	WEEK 2 Initiate treatment
<p>Goal of MDC: Review patient records and determine all necessary diagnostics</p> <p><i>Services may include</i></p> <ul style="list-style-type: none"> • Endobronchial ultrasound (EBUS) • Percutaneous needle biopsy • Positron emission tomography (PET) scans • Pulmonary function tests (PFTs) • Additional imaging 	<p>Goal of MDC: Review diagnostic results, determine treatment plan, and prepare to initiate therapy</p> <p><i>Services may include</i></p> <ul style="list-style-type: none"> • Consults for surgery • Port placement • Additional imaging like magnetic resonance imaging (MRI) • Radiation simulation • Infusion

Importantly, multidisciplinary consensus meetings occur while the patient is in the clinic. This allows patients to leave each appointment with results and next-steps in hand.

Wellstar continues to iterate with process improvements that will cut time to diagnosis and move patients to treatment faster. The STAT Clinic approach has allowed Wellstar to improve survival rates, improve patient satisfaction, and reduce unnecessary testing and visits (reducing total cost).

Results

How we know it's working

In 2022, Wellstar expects about 13,000 patients in their lung cancer detection program. Almost half of those patients came through their newly developed incidental pulmonary nodule program, and the others came through screening. Since beginning their lung cancer program in 2007, Wellstar has reduced time from nodule identification to treatment initiation by 78% to an average of 14 days.

- **Community impact:** Wellstar's lung cancer screening program currently scans around 500-600 patients a month, with 80-120 new patients a month
- **Stage shift:** Approximately 71% of cancers detected are Stage I and II, with about 29% detected at Stages III and IV (compared to a national average of 24% of cancers detected at an early Stage)
- **Experience:** Wellstar's STAT Clinic maintains patient experience scores above the 90th percentile

Having the right approach to lung cancer screening may help save lives. By combining a screening program with incidental finding programs, and managing both efficiently and effectively, Wellstar has been able to do just that.
